

Anhang 4-G: Ergänzende Unterlagen

Subgruppenanalysen der Studien BMN 111-301 und BMN 111-206 (RCT)

Inhaltsverzeichnis

111-206

Efficacy

Height Z-Score	12
Annualized Growth Velocity (cm/year)	84
Upper to Lower Body Segment Ratio	158
Upper Arm Length to Lower Arm (Forearm) Length Ratio	235
Upper Leg Length (Thigh) to Knee to Heel Length Ratio	289
Upper Leg Length (Thigh) to Tibial Leg Length Ratio	343
Arm Span to Standing Height Ratio	397
Interaction	451

Table 14.2.1.2.101.1
Analysis of Covariance of Height Z-Score at Week 52 (Overall), by Sex for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Sex Height Z-Score	Placebo (N=32)	Vosoritide (N=32)
Male		
Baseline		
n	13	16
Mean (SD)	-4.55 (1.65)	-4.06 (1.11)
Median	-4.78	-3.99
25th, 75th Percentile	-5.69, -3.86	-4.67, -3.25
Min, Max	-7.2, -1.9	-5.9, -2.2
Week 52		
n	13	16
Mean (SD)	-4.50 (1.33)	-4.09 (0.84)
Median	-4.29	-4.20

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and sex interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.1.2.101.1
Analysis of Covariance of Height Z-Score at Week 52 (Overall), by Sex for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Sex Height Z-Score	Placebo (N=32)	Vosoritide (N=32)
Female		
Baseline		
n	19	15
Mean (SD)	-4.09 (1.36)	-3.54 (0.75)
Median	-4.02	-3.67
25th, 75th Percentile	-5.41, -3.09	-4.19, -2.94
Min, Max	-6.8, -1.5	-4.8, -2.2
Week 52		
n	19	15
Mean (SD)	-4.52 (1.11)	-3.74 (0.71)
Median	-4.63	-3.85

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and sex interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

P-value for interaction term,treatment * [Ethnicity]		0.7009

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and ethnicity interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.1.2.101.4
Analysis of Covariance of Height Z-Score at Week 52 (Overall), by Baseline AGV for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Baseline AGV Height Z-Score	Placebo (N=32)	Vosoritide (N=32)
SMD (95% CI) ^c		0.41 (-0.70, 1.50)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and AGV interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

P-value ^b		0.7236

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and height z-score interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Analysis of Covariance of Height Z-Score at Week 52 (Cohort 1 ($\geq 24 < 60$ months)), by Ethnicity for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Ethnicity Height Z-Score	Placebo (N=16)	Vosoritide (N=15)
Change from baseline		
n	13	8
Mean (SD)	0.05 (0.54)	0.27 (0.64)
Median	-0.07	0.47
25th, 75th Percentile	-0.34, 0.20	-0.16, 0.72
Min, Max	-0.4, 1.3	-0.8, 0.9
LS mean change from baseline (95% CI)	0.02 (-0.19, 0.22)	0.33 (0.06, 0.60)
Difference in LS mean change from baseline (95% CI) ^a		0.31 (-0.04, 0.67)
P-value ^b		0.0768

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline height z-score, and treatment and ethnicity interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and ≥ 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline AGV and baseline height Z-Score.

For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline height z-score, and treatment and age stratum interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and ≥ 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.3.2.101.1
Analysis of Covariance of Cumulative Annualized Growth Velocity (AGV) at Week 52 (Overall), by Sex for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Sex	Placebo (N=32)	Vosoritide (N=32)
Annualized Growth Velocity (cm/year)		
25th, 75th Percentile	5.67, 7.33	6.88, 9.32
Min, Max	4.8, 9.3	5.8, 11.9

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, and treatment and sex interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, and treatment and ethnicity interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Min, Max	0.3, 4.5	0.6, 4.4
Week 52		
n	12	7
Mean (SD)	5.55 (1.00)	6.06 (1.27)
Median	5.63	6.40

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, and treatment and AGV interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Analysis of Covariance of Cumulative Annualized Growth Velocity (AGV) at Week 52 (Overall), by Baseline Height Z-Score for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Baseline Height Z-Score Annualized Growth Velocity (cm/year)	Placebo (N=32)	Vosoritide (N=32)
> -4		
Baseline		
n	14	18
Mean (SD)	14.71 (8.37)	14.27 (7.23)
Median	15.25	14.13
25th, 75th Percentile	5.14, 23.21	5.94, 20.80
Min, Max	4.4, 29.7	3.9, 25.3
Week 52		
n	14	18
Mean (SD)	9.07 (2.38)	8.84 (2.59)
Median	9.37	9.09

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, and treatment and height z-score interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, and treatment and sex interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and ≥ 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Analysis of Covariance of Cumulative Annualized Growth Velocity (AGV) at Week 52 (Cohort 1 (≥ 24 to < 60 months)), by [Cohort 1]Age stratum for
BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

[Cohort 1]Age stratum Annualized Growth Velocity (cm/year)	Placebo (N=16)	Vosoritide (N=15)
P-value ^b		0.5684
SMD (95% CI) ^c		0.38 (-0.89, 1.63)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, and treatment and age stratum interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and ≥ 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.3.2.102.4

Analysis of Covariance of Cumulative Annualized Growth Velocity (AGV) at Week 52 (Cohort 1 (≥ 24 to < 60 months)), by Baseline AGV for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Baseline AGV Annualized Growth Velocity (cm/year)	Placebo (N=16)	Vosoritide (N=15)
25th, 75th Percentile	5.45, 5.67	5.04, 8.05
Min, Max	4.4, 6.4	2.9, 8.8

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, and treatment and AGV interaction.

Z-Scores were derived using age-sex specific reference data (means and SDs) for average stature children per the Centers for Disease Control and Prevention.

Subjects aged < 24 months, body length takes precedence over standing height. Subjects aged < 24 months at baseline and ≥ 24 months at Week 52, body length takes precedence.

If there was no height assessment within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute missing height/body length.

Note one subject had no height assessment within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and ethnicity interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and age stratum interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.5.2.101.5
Analysis of Covariance of Upper to Lower Body Segment Ratio at Week 52 (Overall), by Baseline Height Z-Score for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Baseline Height Z-Score Upper to Lower Body Segment Ratio	Placebo (N=32)	Vosoritide (N=32)
<= -4		
Baseline		
n	18	13
Mean (SD)	2.43 (0.34)	2.41 (0.27)
Median	2.40	2.42
25th, 75th Percentile	2.22, 2.58	2.23, 2.48
Min, Max	1.9, 3.1	2.0, 3.1

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and height z-score interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and sex interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged ≥ 24 months at baseline and ≥ 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

25th, 75th Percentile	-0.16, 0.04	-0.21, 0.07
Min, Max	-0.2, 0.0	-0.3, 0.3
LS mean change from baseline (95% CI)	-0.60 (-3.28, 2.08)	0.15 (-1.02, 1.32)
Difference in LS mean change from baseline (95% CI) ^a		0.75 (-3.05, 4.56)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and ethnicity interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged < 24 months at baseline and >= 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.5.2.102.3

Analysis of Covariance of Upper to Lower Body Segment Ratio at Week 52 (Cohort 1 (≥ 24 to < 60 months)), by [Cohort 1]Age stratum for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

[Cohort 1]Age stratum Upper to Lower Body Segment Ratio	Placebo (N=16)	Vosoritide (N=15)
--	-------------------	----------------------

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper to lower body segment ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper to lower body segment ratio, and treatment and age stratum interaction.

Subjects aged < 24 months, body length and crown to rump length take precedence over standing height and sitting height. Subjects aged ≥ 24 months at baseline and ≥ 24 months at Week 52, body length and crown to rump length take precedence.

If there was no upper to lower body segment ratio within the Week 52 analysis visit window, but there are assessments before and after Week 52, a linear interpolation using the measurements closest to the before and after Week 52 will be used to impute upper to lower body segment ratio.

Note one subject had no upper to lower body segment ratio within the Week 52 analysis visit nor after Week 52 and was excluded from this analysis.

Table 14.2.5.3.101.1
Analysis of Covariance of Upper Arm Length to Lower Arm (Forearm) Length Ratio at Week 52 (Overall), by Sex for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Sex Upper Arm Length to Lower Arm (Forearm) Length Ratio	Placebo (N=32)	Vosoritide (N=32)
SMD (95% CI) ^c		-0.28 (-1.13, 0.58)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper arm length to lower arm length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline upper arm length to lower arm length ratio, and treatment and sex interaction.

Missing assessments at week 52 were not imputed.

25th, 75th Percentile	1.03, 1.13	1.00, 1.10
Min, Max	1.0, 1.4	0.9, 1.4

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper arm length to lower arm length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper arm length to lower arm length ratio, and treatment and age stratum interaction.

Missing assessments at week 52 were not imputed.

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper arm length to lower arm length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline upper arm length to lower arm length ratio, and treatment and height z-score interaction.

Missing assessments at week 52 were not imputed.

Mean (SD)	1.16 (0.17)	1.11 (0.08)
Median	1.10	1.09
25th, 75th Percentile	1.04, 1.29	1.06, 1.15
Min, Max	1.0, 1.4	1.0, 1.3

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper arm length to lower arm length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper arm length to lower arm length ratio, and treatment and age stratum interaction.

Missing assessments at week 52 were not imputed.

Table 14.2.5.3.102.3

SMD (95% CI) ^c		-0.34 (-1.18, 0.50)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper leg length to knee to heel length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline upper leg length to knee to heel length ratio, and treatment and sex interaction.

Missing assessments at week 52 were not imputed.

Analysis of Covariance of Upper Leg Length (Thigh) to Knee to Heel Length Ratio at Week 52 (Cohort 1 (≥ 24 to < 60 months)), by [Cohort 1]Age stratum for BMN111-206

Analysis Population: Full Analysis Set (Randomized Subjects)

[Cohort 1]Age stratum Upper Leg Length (Thigh) to Knee to Heel Length Ratio	Placebo (N=16)	Vosoritide (N=15)
≥ 24 months to < 36 months		
Baseline		
n	4	8
Mean (SD)	0.66 (0.09)	0.61 (0.10)
Median	0.67	0.64
25th, 75th Percentile	0.59, 0.72	0.55, 0.68
Min, Max	0.5, 0.7	0.4, 0.7
Week 52		
n	4	8
Mean (SD)	0.65 (0.05)	0.64 (0.08)
Median	0.65	0.66
25th, 75th Percentile	0.61, 0.69	0.60, 0.71
Min, Max	0.6, 0.7	0.5, 0.7

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper leg length to knee to heel length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper leg length to knee to heel length ratio, and treatment and age stratum interaction.

Missing assessments at week 52 were not imputed.

Table 14.2.5.5.101.1
Analysis of Covariance of Upper Leg Length (Thigh) to Tibial Length Ratio at Week 52 (Overall), by Sex for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Sex Upper Leg Length (Thigh) to Tibial Leg Length Ratio	Placebo (N=32)	Vosoritide (N=32)
Change from baseline		
n	13	14
Mean (SD)	0.00 (0.24)	-0.08 (0.16)
Median	0.02	-0.07
25th, 75th Percentile	-0.01, 0.07	-0.19, 0.00
Min, Max	-0.6, 0.5	-0.4, 0.2
LS mean change from baseline (95% CI)	-0.01 (-0.07, 0.06)	-0.07 (-0.13, -0.01)
Difference in LS mean change from baseline (95% CI) ^a		-0.06 (-0.16, 0.03)
P-value ^b		0.1699

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper leg length to tibial leg length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline upper leg length to tibial leg length ratio, and treatment and sex interaction.

Missing assessments at week 52 were not imputed.

Analysis of Covariance of Upper Leg Length (Thigh) to Tibial Length Ratio at Week 52 (Overall), by [Cohort 1]Age stratum for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

[Cohort 1]Age stratum Upper Leg Length (Thigh) to Tibial Leg Length Ratio	Placebo (N=32)	Vosoritide (N=32)
SMD (95% CI) ^c		-0.11 (-1.36, 1.14)

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper leg length to tibial leg length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, baseline age, baseline AGV, baseline upper leg length to tibial leg length ratio, and treatment and age stratum interaction.

Missing assessments at week 52 were not imputed.

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline upper leg length to tibial leg length ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline upper leg length to tibial leg length ratio, and treatment and ethnicity interaction.

Missing assessments at week 52 were not imputed.

25th, 75th Percentile	0.87, 0.90	0.86, 0.90
Min, Max	0.8, 0.9	0.8, 0.9

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline arm span to standing height ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline arm span to standing height ratio, and treatment and sex interaction.

Missing assessments at week 52 were not imputed.

SMD (95% CI) ^c		-2.33 (-4.06, -0.53)
P-value for interaction term, treatment * [Sex]		0.4371

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline arm span to standing height ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include age stratum, baseline age, baseline AGV, baseline arm span to standing height ratio, and treatment and sex interaction.

Missing assessments at week 52 were not imputed.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline arm span to standing height ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline arm span to standing height ratio, and treatment and AGV interaction.

Missing assessments at week 52 were not imputed.

Table 14.2.5.6.102.4
Analysis of Covariance of Arm Span to Standing Height Ratio at Week 52 (Cohort 1 (≥ 24 to < 60 months)), by Baseline AGV for BMN111-206
Analysis Population: Full Analysis Set (Randomized Subjects)

Baseline AGV Arm Span to Standing Height Ratio	Placebo (N=16)	Vosoritide (N=15)
SMD (95% CI) ^c		-0.85 (-2.22, 0.57)
P-value for interaction term,treatment * [Baseline AGV]		0.2443

^a Difference is vosoritide minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. Model terms included treatment, sex, age stratum, baseline age, baseline arm span to standing height ratio, and baseline AGV. For the overall analysis, which includes the interaction-term, model terms include sex, age stratum, baseline age, baseline AGV, baseline arm span to standing height ratio, and treatment and AGV interaction.

Missing assessments at week 52 were not imputed.

Table 14.2.13.1.2.101
Infant Toddler Quality of Life (ITQoL): Overall Health Score (Overall) by Sex for BMN111-206
Analysis Population: Full Analysis Set

Sex Score Visit Result	Placebo (N=32)	Vosoritide (N=32)
Male		
ITQoL : Overall Health Score		
Baseline		
n	11	17
Mean (SD)	86.4 (17.9)	81.2 (15.4)
Median	100.0	85.0
25th, 75th Percentile	60.0, 100.0	60.0, 85.0
Min, Max	60, 100	60, 100
Week 26		
n	12	15
Mean (SD)	85.8 (14.0)	83.3 (21.4)
Median	85.0	85.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Hedges'g (95% CI) ^c		-1.33 (-3.11, 0.55)
P-value for interaction term, treatment * [Ethnicity]		0.2568

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

25th, 75th Percentile	85.0, 100.0	85.0, 100.0
Min, Max	60, 100	60, 100
Week 26		
n	11	7
Mean (SD)	92.3 (12.7)	90.0 (15.0)
Median	100.0	100.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Difference in change from baseline (95%CI)		7.36 (-28.80, 43.51)
P-value ^b		0.6363
Hedges'g (95% CI) ^c		0.28 (-0.83, 1.37)

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Week 52		
n	11	6
Mean (SD)	70.1 (25.3)	81.7 (21.8)
Median	80.0	88.3

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Difference in change from baseline (95%CI)		8.71 (-3.15, 20.56)
P-value ^b		0.1301
Hedges'g (95% CI) ^c		0.62 (-0.60, 1.81)
P-value for interaction term, treatment * [Baseline AGV Category]		0.6517

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Median	80.0	85.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Median	83.3	100.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Difference in change from baseline (95%CI)		-4.57 (-11.24, 2.11)
P-value ^b		0.1718
Hedges'g (95% CI) ^c		-0.52 (-1.27, 0.24)

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

n	11	6
Mean (SD)	88.6 (15.7)	81.7 (29.9)
Median	100.0	100.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Difference in change from baseline (95%CI)		0.64 (-15.87, 17.14)
P-value ^b		0.9372
Hedges'g (95% CI) ^c		0.03 (-0.75, 0.81)

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Week 52		
n	12	7
Mean (SD)	3.5 (0.7)	4.1 (0.9)
Median	3.0	4.0

Max, maximum; Min, minimum; SD, standard deviation; NE, not estimable.

A higher score reflects a higher quality of life.

^a Change from baseline was based on the subjects with available measurements at both time points. Baseline is defined as Day 1 or screening if a Day 1 assessment is not available.

^b Two-sided p-value.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

^c An effect size that represents standardized mean difference (SMD). The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

The p-value for the interaction term is based from an analysis of variance model, which only includes the terms used for interaction as covariates.

Analysis Population: Safety Analysis Set

System Organ Class Preferred Term	Placebo (N=25)	Vosoritide (N=29)	RR [95%CI] p-value	OR [95%CI] p-value	RD [95%CI] p-value
Subjects with any AE, n (%) ^a	25 (100.0)	29 (100.0)	NA	NA	NA
Injection site reaction	12 (48.0)	27 (93.1)	1.94 (1.27; 2.95) 0.0020	14.63 (2.85; 75.14) 0.0013	0.4510 (0.23; 0.67) 0.0000
Injection site erythema	12 (48.0)	25 (86.2)	1.80 (1.16; 2.77) 0.0081	6.77 (1.82; 25.22) 0.0044	0.3821 (0.15; 0.61) 0.0013
Gastrointestinal disorders, n (%) ^a	20 (80.0)	19 (65.5)	0.82 (0.59; 1.14)	0.48 (0.14; 1.65)	-0.1448 (-0.38; 0.09)

AE, adverse event; EOI, event of interest; CTCAE, common terminology criteria for adverse events; MedDRA, Medical Dictionary for Regulatory Activities; NCI, National Cancer Institute; SAE, serious adverse event; RR, relative risk; OR, odds ratio; RD, risk difference; NA, not applicable or not presented.

AEs with onset or worsening after the initiation of study drug and up to 30 days after study drug discontinuation were included. AEs were coded using MedDRA version [Multiple] and graded for severity using NCI CTCAE version 4.0.

^a Percentages were calculated using the total number of subjects in the safety population (N for each treatment group) as the denominator. Subjects with more than one AE of the same category were counted only once for that category.

Table 14.2.1.7.1
Analysis of Covariance of Annualized Growth Velocity (cm/year) at Week 52 by Sex for BMN111-301
Analysis Population: Full Analysis Set

Sex Annualized Growth Velocity (cm/year)	Placebo (N=61)	15 ug/kg BMN 111 (N=60)
Male		
Baseline		
n	33	31
Mean (SD)	3.85 (1.15)	4.02 (1.78)
Median	3.93	3.97
25th, 75th Percentile	3.11, 4.57	2.97, 5.42
Min, Max	1.5, 5.9	-0.1, 6.9
Week 52		
n	33	31
Mean (SD)	4.12 (0.94)	5.53 (1.26)
Median	4.10	5.74
25th, 75th Percentile	3.58, 4.63	4.97, 6.37

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and sex interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

25th, 75th Percentile	2.95, 4.29	5.37, 6.29

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and age interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

Table 14.2.1.10.1
Analysis of Covariance of Annualized Growth Velocity (cm/year) at Week 52 by Strata for BMN111-301
Analysis Population: Full Analysis Set

Strata Annualized Growth Velocity (cm/year)	Placebo (N=61)	15 ug/kg BMN 111 (N=60)
Male Tanner Stage I		
Baseline		
n	28	28
Mean (SD)	3.93 (1.19)	3.80 (1.72)
Median	4.11	3.87
25th, 75th Percentile	3.25, 4.73	2.90, 4.96
Min, Max	1.5, 5.9	-0.1, 6.9
Week 52		
n	28	28
Mean (SD)	4.12 (0.93)	5.41 (1.19)
Median	4.04	5.66
25th, 75th Percentile	3.51, 4.63	4.83, 6.33

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and stratum interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

SMD (95% CI) ^c		1.58 (0.24, 2.87)
P-value for interaction term, treatment * [Strata]		0.2055

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and stratum interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and height z-score interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

Analysis of Covariance of Annualized Growth Velocity (cm/year) at Week 52 by Ethnicity for BMN111-301
Analysis Population: Full Analysis Set

Ethnicity Annualized Growth Velocity (cm/year)	Placebo (N=61)	15 ug/kg BMN 111 (N=60)
Min, Max	1.3, 6.5	2.3, 8.4
Change from baseline		
n	41	45
Mean (SD)	-0.12 (1.77)	1.52 (1.72)
Median	-0.31	1.65
25th, 75th Percentile	-1.46, 0.62	-0.11, 2.59
Min, Max	-3.0, 4.5	-1.7, 6.5
LS mean change from baseline (95% CI)	0.12 (-0.31, 0.55)	1.73 (1.32, 2.14)
Difference in LS mean change from baseline (95% CI) ^a		1.61 (1.14, 2.08)

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and ethnicity interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and region interaction.

AGV at a Post-baseline Visit is defined as [(Height at Post-baseline Visit - Height at Baseline)/(Date of Post-baseline Visit - Date of Baseline Assessment)] x 365.25.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and age interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

Difference in LS mean change from baseline (95% CI) ^a		0.00 (-0.33, 0.34)
P-value ^b		0.9780

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and tanner stage interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and stratum interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

Table 14.2.2.11.1
Analysis of Covariance of Height Z-Score at Week 52 by Baseline Height Z-score for BMN111-301
Analysis Population: Full Analysis Set

Baseline Height Z-score Height Z-Score	Placebo (N=61)	15 ug/kg BMN 111 (N=60)
SMD (95% CI) ^c		1.11 (-1.10, 3.22)
P-value for interaction term, treatment * [Baseline Height Z-score]		0.4818

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and height z-score interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and ethnicity interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

NE, Not estimable.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and region interaction.

Missing standing height at Week 52 (i.e. Day 365) will be imputed by applying the baseline AGV (cm/yr) to the last available height assessment. Based on this imputed standing height, the height z-score and AGV at Week 52 will be calculated.

^a Difference is 15ug/kg BMN 111 minus placebo. ^b Two-sided p-value.

^c SMD (standardized mean difference) is an effect size measure similar to hedges g; however, this SMD is based on a least squares mean from a general linear model. The two-sided confidence interval of the SMD is based on a noncentral t-distribution.

LS means and difference in LS means were obtained from an analysis of covariance model. For the by-stratum analysis, model terms included stratum defined by sex and Tanner stage, treatment, baseline age, baseline AGV and baseline height z-score. For the overall analysis, which includes the interaction-term, model terms include baseline age, baseline AGV, baseline height z-score, and treatment and age interaction.

Missing sitting height and standing height at Week 52 will be imputed by applying the baseline AGV for sitting height and standing height to the last available sitting/standing height assessment. Based on this imputed sitting height and standing height at Week 52, the upper:lower body segment ratio will be calculated. See SAP for additional imputation details.
